

Appendix: The mobilisation potential of anti-containment protests in Germany

Sophia Hunger, Swen Hutter, and Eylem Kanol

2023-01-04

Abstract

The Covid-19 pandemic triggered polarisation across Europe. While most citizens supported the governments’ containment measures, others took to the streets and voiced their dissatisfaction. The paper focuses on the mobilisation potential related to this het-erogenous protest wave. It examines individuals that show sympathy and are willing to engage in anti-containment demonstrations based on sixteen waves of a rolling cross-section survey fielded in Germany in 2020/2021. The results show a considerable and stable mobilisation potential: Every fifth respondent sympathises with the protesters, and around 60 percent of those are ready to participate themselves. Political distrust, far-right orientations, and an emerging ‘freedom divide’ structure the potential, as do Covid-19-related economic and health threats. Moreover, the findings indicate a radi-calisation process and show how ideology and threat perceptions drive the step from sympathy to willingness to participate, suggesting that ideological polarisation may quickly spill over to the streets given an appropriate supply of protest opportunities.

6 Interactions for different time periods

Lastly, we interact the two main periods of the time frame under analysis with our main explanatory variables: ideology, extreme ideology, trust in government, economic and health risks. The interactions for ideology and trust in government are included in the main paper. The interactions plots for extreme ideology as well as economic and health threats can be found below. We consider two main splits within our time frame: before August 2020, after August 2020 and observations in the year 2021. The first split is marked by large protests in several German cities. These protests received a lot of public and media attention due to several radical and violent action forms, most notably when demonstrators tried to enter the parliamentary building of the German Bundestag. The split between fall 2020 and spring 2021 is characterized by the further radicalization and two lockdowns. This allows us to test the consistency of our findings against the dynamically evolving situation of the protests. We find several differences in the driving factors of protest support and willingness to participate between the three time periods.

Figure 4: Predicted probabilities for sympathy

Figure 5: Predicted probabilities for willingness to protest

8 Robustness check: Political trust

Since most of our data includes a measure of political trust that is closely related to the pandemic, we perform additional robustness checks using two items that asks for distrust in politicians and political parties, which were, however, only included on the later waves. The models below show that the results are consistent with our main models regarding sympathy for the anti-containment protest (model 1 and 3 in table 7). For willingness to participate, the significance, however, vanishes (model 2 and 4).

Table 7: Regression Results (odds ratios)

	<i>Dependent variable:</i>			
	support (1)	participate (2)	support (3)	participate (4)

9 Robustness check: Multilevel models

As robustness checks, we also ran multilevel models despite the small number of upper level clusters (number of waves = 16). However, the intraclass correlation coefficient for both main dependent variables are very low (see graphs 5 and 6): 0.02 for protest sympathy, 0.01 for willingness to protest. We nevertheless estimated multilevel models with random effects at the upper level. The revised appendix includes these (section 11). The results confirm the main findings from our main models.

9.1 Cluster variance - Protest sympathy

Figure 6: ICC for sympathy

9.2 Cluster variance - Protest willingness

Figure 7: ICC for willingness to protest

9.3 Multi-level models
